

FFR in diffuse disease and serial stenoses

Educational Training Program ESC
European Heart House
Apr. 25-27 2013

Nils Witt
MD PhD, Södersjukhuset, Stockholm, Sweden

Single stenosis

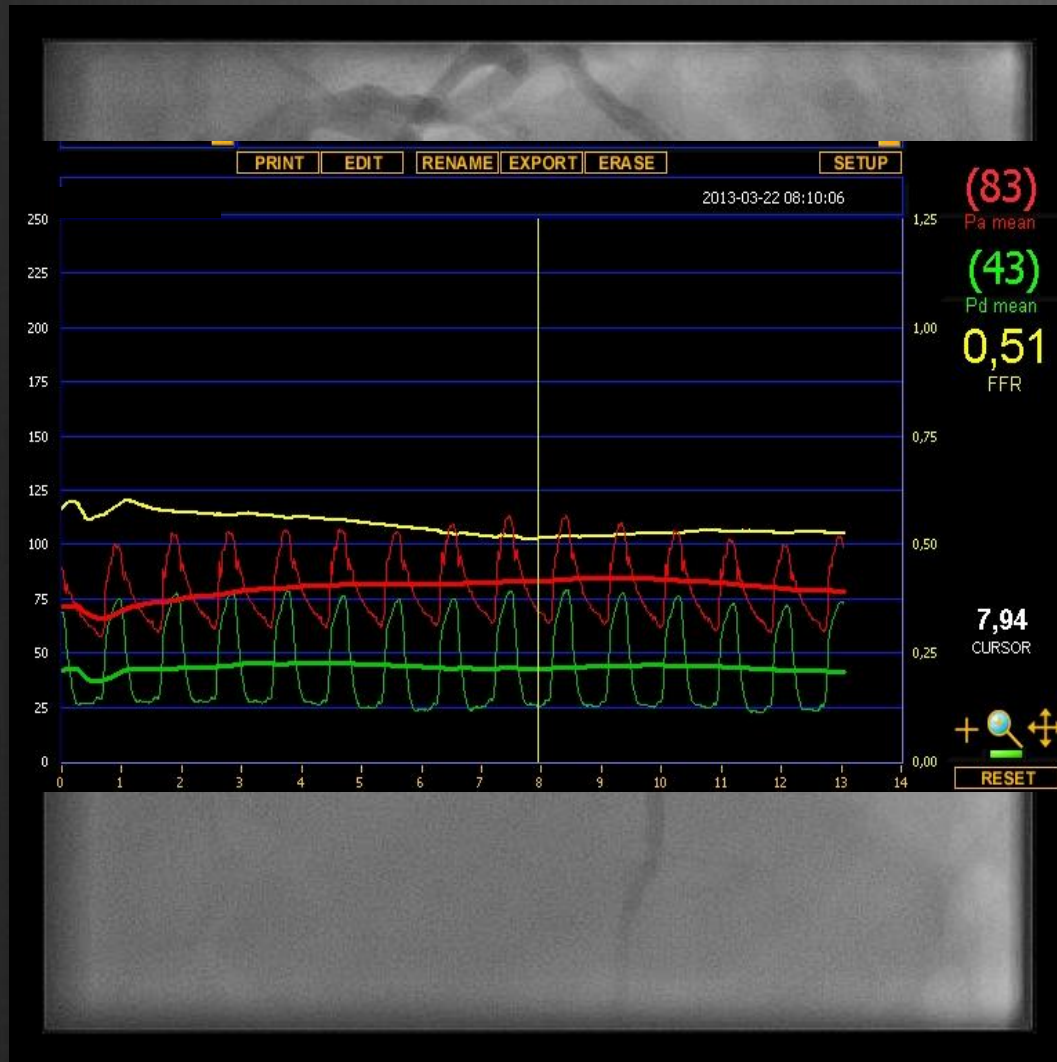

66 y.o. Female
with
hypertension and
6 months history
of angina.

Single stenosis

- ⊗ Functional severity of a focal stenosis in an otherwise non-diseased vessel is easily assessed by the ratio between distal and proximal pressure, P_d/P_a during maximum hyperemia (FFR)
- ⊗ No substantial change in FFR in different positions distal to the stenosis
- ⊗ Functional result after PCI is highly predictable

Serial stenoses

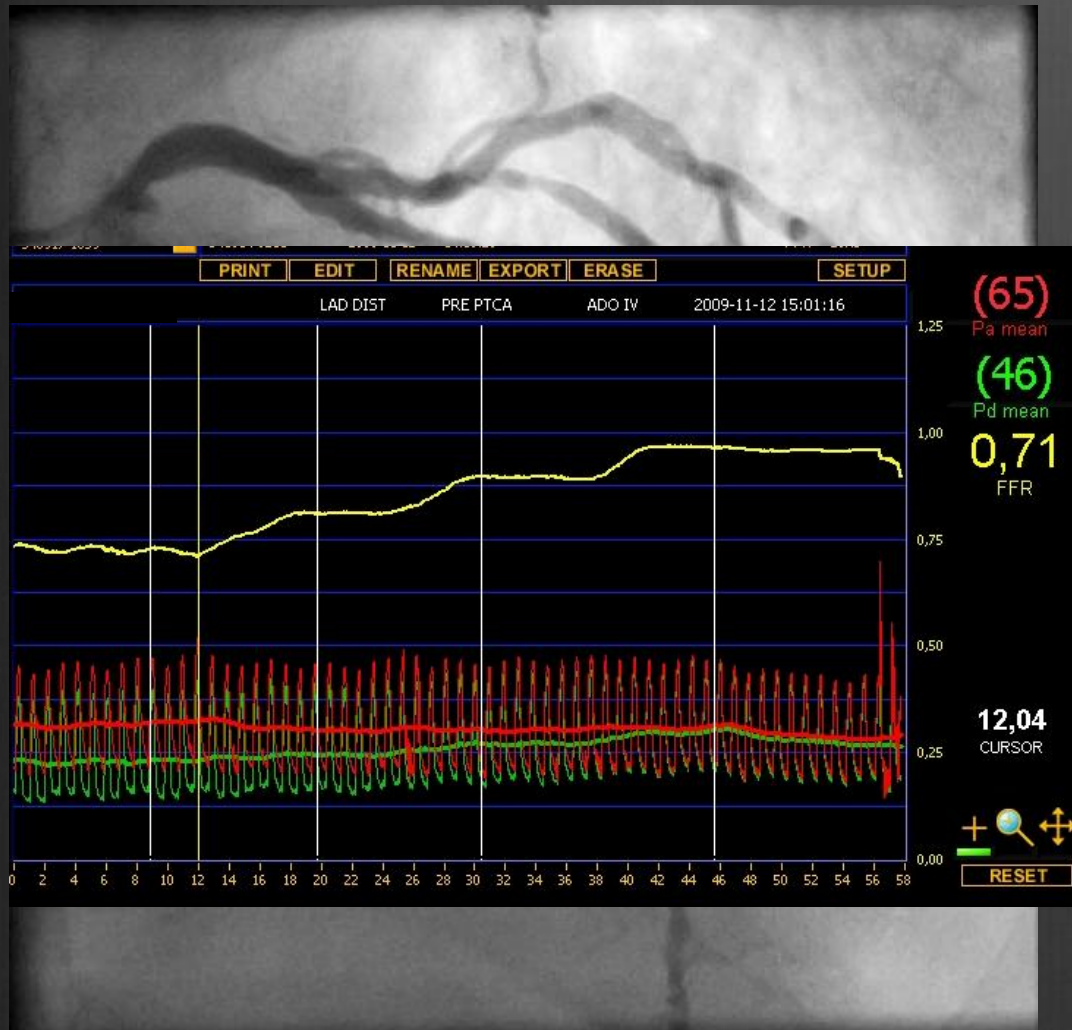

59 y.o. Male with angina CCS 3 and a perfusion scan showing apical/septal reversible perfusion defects.

Serial stenoses

- ⊗ In the presence of multiple lesions within the same vessel, fluid dynamic interaction between the stenoses complicates the assessment of functional severity
- ⊗ The individual contribution of each stenosis to "total" FFR is not easily predicted
- ⊗ Complex lesions, if functionally *significant*, may affect the choice of treatment strategy (favouring CABG)
- ⊗ Complex lesions, if functionally *non-significant*, should be left untouched (favouring PCI in remaining lesions)

Diffuse disease

48 y.o. Male with angina CCS 2 and a positive bicycle stress test.

Diffuse disease

- ⊗ Diffuse atherosclerotic disease adds further complexity to the assessment of functional severity
- ⊗ Flow limitation may be predominantly caused by long diffusely diseased segments despite more conspicuous focal lesions (PCI will not help)
- ⊗ Significant gradients may exist even in the absence of focal lesions

Coronary pressure in the presence
of serial lesions.

Induction of maximum hyperemic flow is a fundamental basis of FFR. A second proximal or distal stenosis potentially limits maximum flow, thereby changing this prerequisite.

The "apparent" FFR of each stenosis may be expressed as:

- $FFR(A)_{app} = P_m / P_a$
- $FFR(B)_{app} = P_d / P_m$

The FFR of individual lesions may be *predicted* by applying fluid dynamic theory, incorporating the coronary wedge pressure;

$$FFR(A)_{pred} = \frac{P_d - (P_m / P_a) P_w}{P_a - P_m + P_d - P_w}$$

$$FFR(B)_{pred} = 1 - \frac{(P_a - P_w)(P_m - P_d)}{P_a (P_m - P_w)}$$

Pressure-Derived Fractional Flow Reserve to Assess Serial Epicardial Stenoses

Theoretical Basis and Animal Validation

Bernard De Bruyne, MD, PhD; Nico H.J. Pijls, MD, PhD; Guy R. Heyndrickx, MD, PhD;
Dominique Hodeige, MD; Richard Kirkeeide, PhD; K. Lance Gould, MD

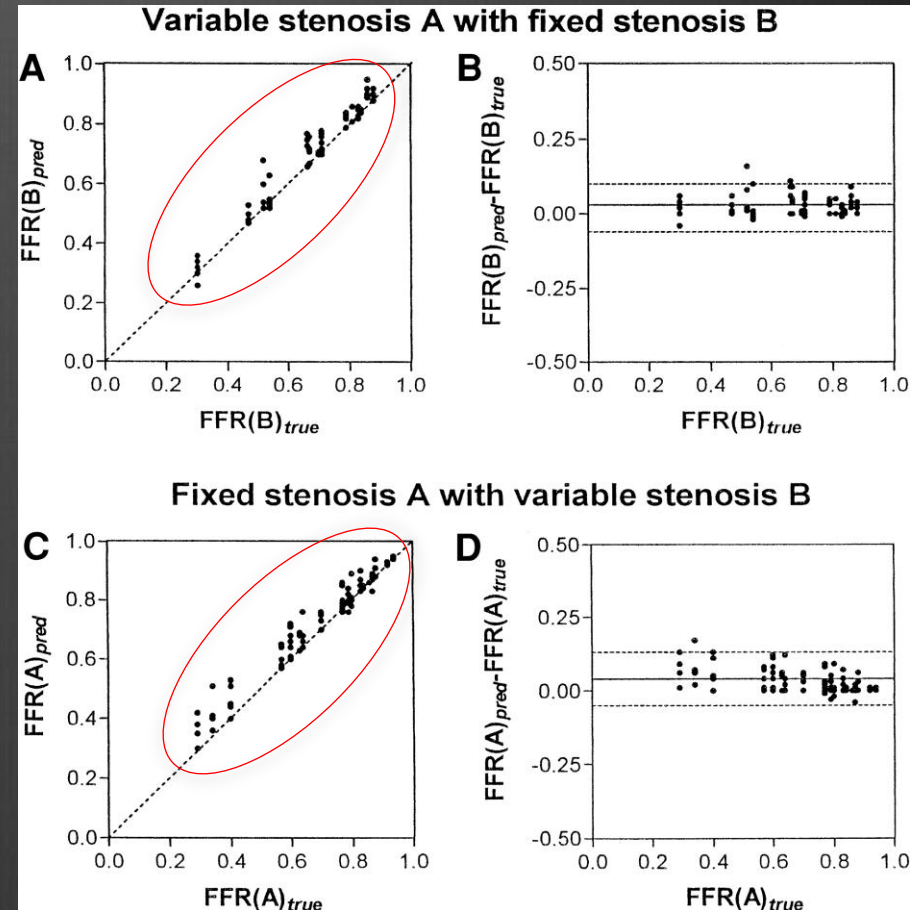

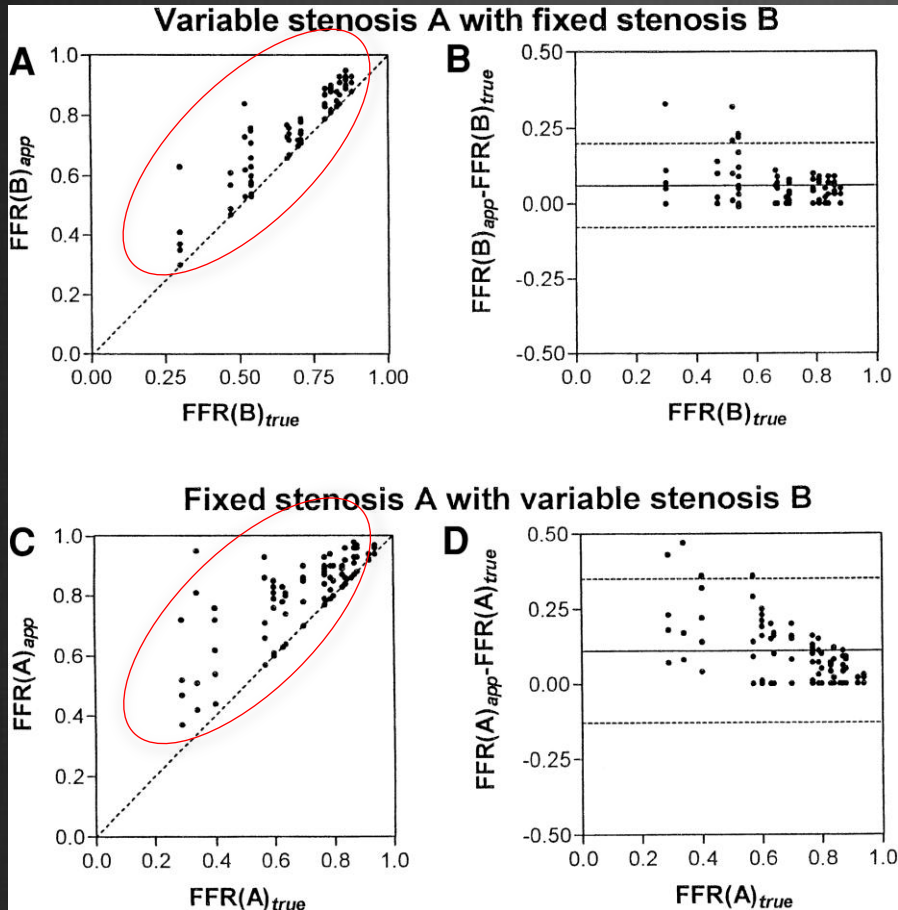

Open chest dogs, 2 stenoses of varying severity.

$$\text{FFR}(A)_{\text{pred}} = \frac{P_d - (P_m/P_a) P_w}{P_a - P_m + P_d - P_w}$$

$$\text{FFR}(B)_{\text{pred}} = 1 - \frac{(P_a - P_w)(P_m - P_d)}{P_a(P_m - P_w)}$$

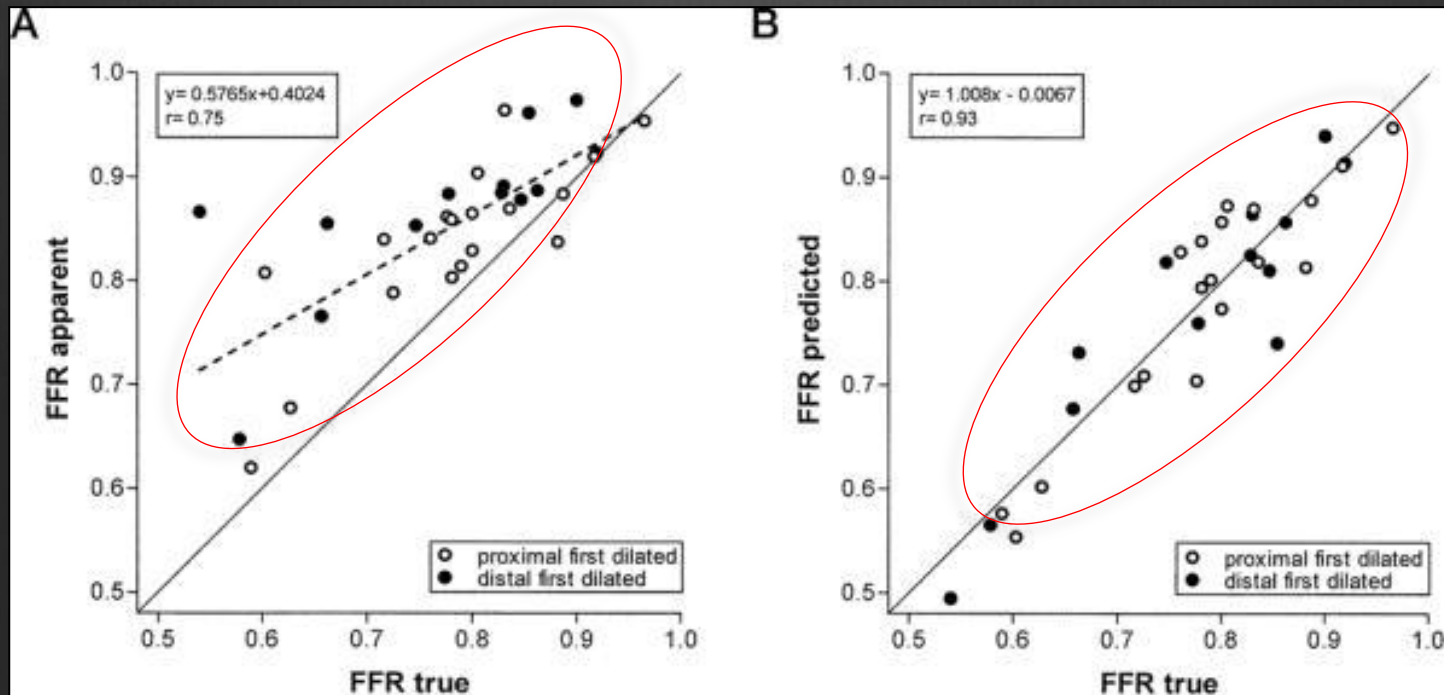

FFR_{app} and FFR_{pred} vs FFR_{true} in cases of one fixed and one variable stenosis.

**Coronary Pressure Measurement to Assess the
Hemodynamic Significance of Serial Stenoses Within
One Coronary Artery
Validation in Humans**

Nico H.J. Pijls, MD, PhD; Bernard De Bruyne, MD, PhD; G. Jan Willem Bech, MD;
Francesco Liistro, MD; Guy R. Heyndrickx, MD, PhD;
Hans J.R.M. Bonnier, MD, PhD; Jacques J. Koolen, MD, PhD

- 32 patients with ≥ 2 lesions in one vessel
- Pressure pull-back
- PTCA of most severe + wedge pressure
- Re-measure after removal of one stenosis

$$\frac{P_d - (P_m / P_a) P_w}{P_a - P_m + P_d - P_w}$$

Practical approach: the pressure pull-back recording

The pressure pull-back recording

- ⦿ Continuous infusion of Adenosine 140 $\mu\text{g/kg/min}$.
- ⦿ Steady state maximum hyperemia after app. 1 min.
- ⦿ Chest discomfort / dyspnea (instruct the patient to breathe normally)
- ⦿ Slight (10-15%) decline in blood pressure

The pressure pull-back recording

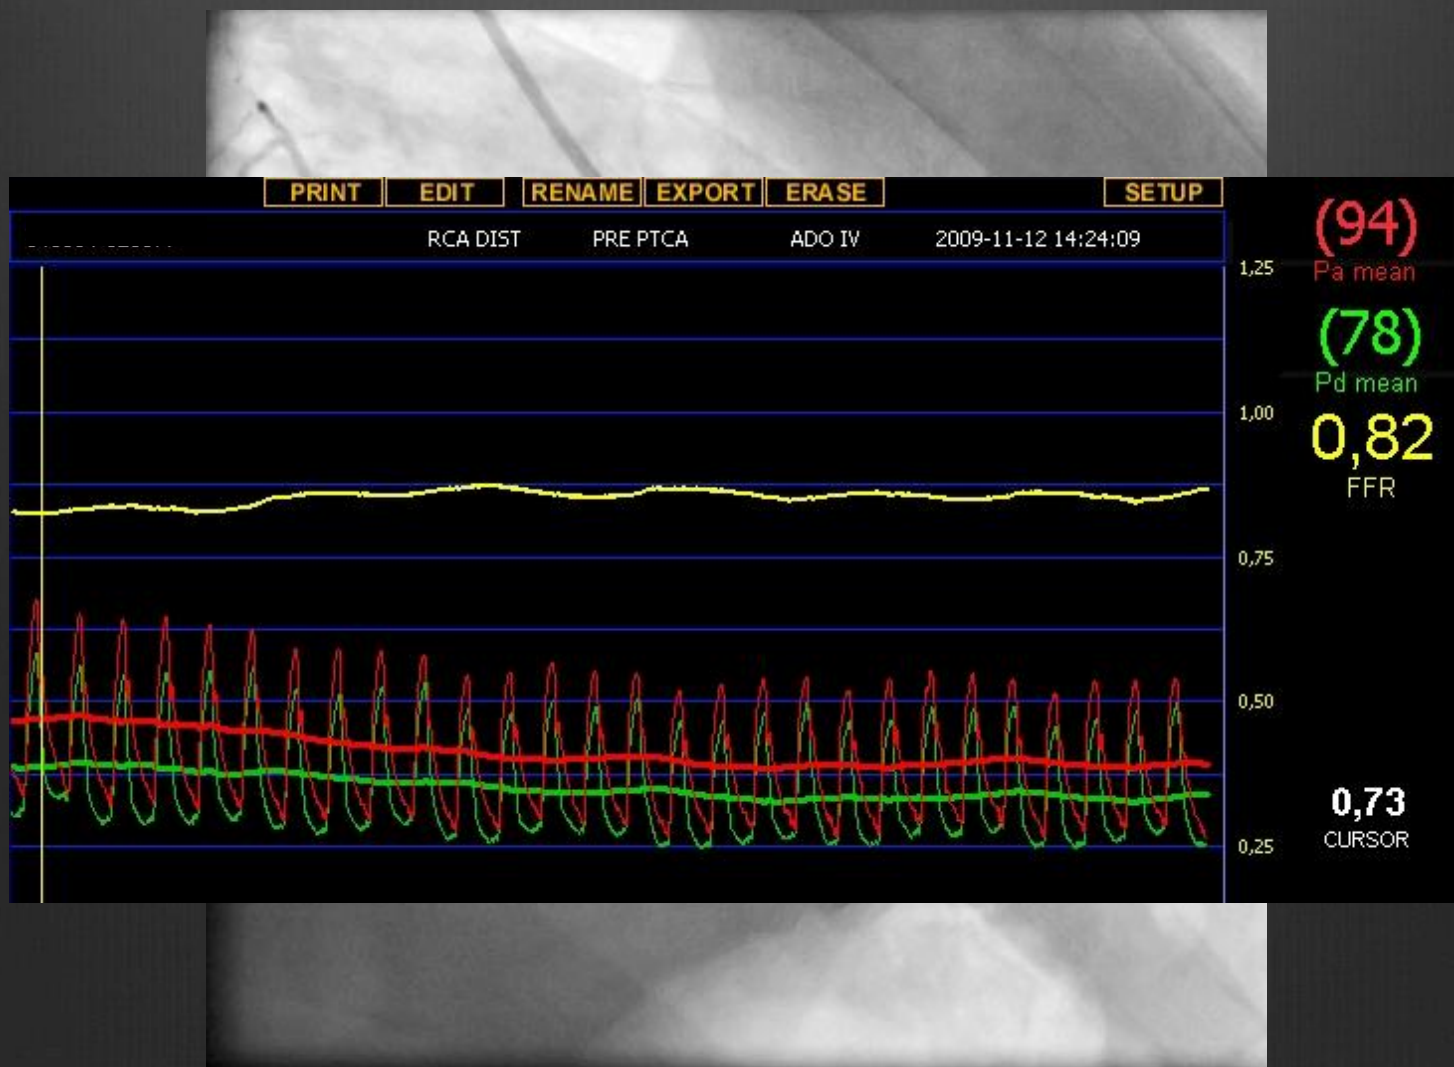

- ⦿ Slow pull-back of the pressure wire during fluoroscopy in order to correlate pressure with anatomy
- ⦿ Check equalizing position (should be 1,0!)
- ⦿ Analyze recording

The pressure pull-back recording

- ⦿ Focal step-up?
- ⦿ Diffuse disease without focal step-up?
- ⦿ Combination?
- ⦿ Clinical decision (PCI / CABG / OMT)
- ⦿ If PCI, start with lesions producing the largest pressure step-up
- ⦿ Repeat measurements after each treated segment and continue until FFR > 0,80

48 y.o. Male with angina
CCS 2 and a positive
bicycle stress test.

MINI-FOCUS ON FRACTIONAL FLOW RESERVE
Clinical Research

Clinical and Physiological Outcomes of Fractional Flow Reserve-Guided Percutaneous Coronary Intervention in Patients With Serial Stenoses Within One Coronary Artery

Hack-Lyoung Kim, MD,* Bon-Kwon Koo, MD, PhD,* Chang-Wook Nam, MD, PhD,† Joon-Hyung Doh, MD, PhD,‡ Ji-Hyun Kim, MD,§ Han-Mo Yang, MD, PhD,* Kyung-Woo Park, MD, PhD,* Hae-Young Lee, MD, PhD,* Hyun-Jae Kang, MD, PhD,* Young-Seok Cho, MD, PhD,|| Tae-Jin Youn, MD, PhD,|| Sang-Hyun Kim, MD, PhD,¶ In-Ho Chae, MD, PhD,|| Dong-Ju Choi, MD, PhD,|| Hyo-Soo Kim, MD, PhD,* Byung-Hee Oh, MD, PhD,* Young-Bae Park, MD, PhD*

- ⊗ 131 patients with multiple lesions within the same artery
- ⊗ Composite FFR < 0,80
- ⊗ Pressure pullback
- ⊗ Primary culprit = largest pressure step-up
- ⊗ Repeat pullback after PCI
- ⊗ Repeat PCI until FFR > 0,80

Apparent vs true FFR in serial stenoses

Clinical outcome (509 days)

- ⦿ No events related to deferred lesions
- ⦿ One target vessel revasc (in-stent restenosis)
- ⦿ One nontarget vessel-related MI
- ⦿ One noncardiac death

Summary

- ⦿ Serial stenoses and diffuse disease represent a challenging diagnostic situation, often accompanied by therapeutic dilemmas
- ⦿ The contribution of individual lesions and diffusely diseased segments to "total FFR" is not easily appreciated at a first glance
- ⦿ Theoretical models accurately predict "true FFR" in serial lesions
- ⦿ In clinical practice, pull-back recordings with i.v. adenosine offer a useful diagnostic tool, permitting stepwise procedures with appropriate stenting of functionally significant lesions
